Abstract: In this paper we introduce, numerical computation of some iterative techniques for solving system of linear simultaneous equations of 4 or more variables. Many iterative techniques is presented by the different formulae. Using Jacobi method, Seidel method and SOR method and their results are compared. The software, Matlab 2009a was used to find the solution of the linear simultaneous equations having diagonally dominant in coefficient matrix. Numerical rate of convergence of solution has been found in each calculation. It was observed that the Seidel method converges at the 12 iteration while Jacobi and SOR methods converge to the exact value of $\mathrm{X}(\mathrm{x}, \mathrm{y}, \mathrm{z}, \mathrm{t})$ with error level of accuracy $10^{-15}$ at the 22th iteration respectively. However, when we compare performance, we must compare both cost, speed of convergence. Some numerical examples are given to illustrate the efficiency and robustness of the techniques. It was then concluded that Seidel is the most effective technique.

Keywords: iterative techniques; algorithm; linear simultaneous equations on large scale; rate of convergence; numerical experiments, executing time.

## 1. Introduction

Solving system of linear simultaneous equations is one of the most important and challenging problems in science and engineering applications. It arises in a wide variety of practical applications in Physics, Chemistry, Biosciences, Engineering, etc. System of linear equations arises in various theoretical research fields as well as applications in science and engineering. After the availability of computers, we go to numerical methods which are suited for computer

[^0]operations. Well known techniques of linear algebra such as Gaussian elimination and Gauss Jordon's methods are utilized to determine a common solution. Specifically, the problem of existence, uniqueness and cardinality of solution of a system of linear equations is well solved in linear algebra. In linear algebra, Iterative solver is an algorithm [1] that can be used to determine the solutions of a system of linear equations to find the rank of a matrix [3-5], and to calculate the inverse of an invertible square matrix. Another point of view, which turns out to be very useful to analyze the algorithm. The first part of the algorithm computes an LU decomposition (it is a matrix decomposition which writes a matrix as the product of a lower triangular matrix and an upper triangular matrix. A linear equation system is a set of linear equations to be solved simultaneously. This system consists of linear equations, each with coefficients, and has unknowns which have to fulfill the set of equations simultaneously. To simplify notation, it is possible to rewrite the equations in matrix notation which are diagonally dominant in coefficients matrix.[6-8] .Consider a system of n linear algebraic equations in n unknowns where $(\mathrm{m}=\mathrm{n})$
\[

$$
\begin{gather*}
a_{11} x_{1}+a_{12} x_{2}+\cdots \ldots \ldots . a_{1 n} x_{n}=b_{1} \\
a_{21} x_{1}+a_{22} x_{2}+\ldots \ldots \ldots . a_{2 n} x_{n}=b_{2} \\
\ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots . . \ldots \ldots \ldots a_{m n} x_{n}=b_{m} \\
a_{m 1} x_{1}+a_{m 2} x_{2}+\ldots \ldots \ldots \ldots \tag{i}
\end{gather*}
$$
\]

Where $a_{i j},\left(i, j=1(1) n\right.$ are the known coefficient, $b_{i,}(\mathrm{i}=1(1) \mathrm{n})$ are the known values and $x_{i},(\mathrm{i}=1(1) \mathrm{n})$ are the unknowns to be determined. In matrix notation the system can be written as
where

$$
\begin{gather*}
\mathrm{Ax}=\mathrm{b}  \tag{ii}\\
\mathrm{~A}=\left[\begin{array}{ccc}
a_{11} & a_{12} & a_{13} \\
a_{21} & a_{22} & a_{23} \\
\ldots \ldots & \ldots \ldots & \ldots \ldots \\
a_{m 1} & a_{m 2} & a_{m n}
\end{array}\right]
\end{gather*}
$$

The matrix $[A: b]$ is called the augmented matrix. It is formed by appending the column b to the $m \times n$ matrix. The methods of solution of the linear algebraic equations (ii) may broadly be classified into two types. (i) Direct methods: These methods produce the exact solution after a finite number of steps. (ii) Iterative methods: These methods give a sequence of approximate solutions, which converges when the number of steps tends to infinity. Here we are interested in the case when $\mathrm{m}=\mathrm{n}$; particularly when the number of equations are large. A took-kit to solve equations of this type is at the heart of the numerical analysis. Before we present the numerical
methods to solve equation (ii), we have to know the conditions under which the solutions exist. We then proceed to develop direct and iterative methods for solving large scale problems. We later discuss numerical conditioning of a matrix and its relation to errors that can arise in computing numerical solutions.[6]

## 2. Iterative Techniques

By this approach, we start with some initial guess solution, say $x^{(0)}$, for solution x and generate an improved solution estimate $x^{(k+1)}$ from the previous approximation $\mathrm{x}^{(\mathrm{k})}$. This method is a very effective for solving differential equations, integral equations and related problems [4]. Let the residue vector $r$ be defined as

$$
\begin{equation*}
r_{i}^{(k)}=b_{i}-\sum_{j=1}^{n} a_{i j} x_{j}^{(k)} \quad \text { for } \mathrm{i}=1,2, \ldots . \mathrm{n} \tag{3}
\end{equation*}
$$

ie. $r^{(k)}=b-A x^{(k)}$ The iteration sequence $\left\{x^{(k)}: k=0,1, \ldots \ldots\right\}$ is terminated when some norm of the residue $\quad\left\|r^{(k)}\right\|=\left\|A x^{(k)}-\mathrm{b}\right\| \quad$ becomes sufficiently small, ie.

$$
\begin{equation*}
\left\|\frac{r^{(k)}}{b}\right\|<\epsilon \tag{4}
\end{equation*}
$$

Where $\epsilon$ is an arbitrarily small number as $\varepsilon=10^{-15}$ another possible termination criterion can be

$$
\begin{equation*}
\left\|\frac{x^{(k)}-x^{(k+1)}}{x^{(k+1)}}\right\|<\epsilon \tag{5}
\end{equation*}
$$

It may be noted that the later condition is practically equivalent to the previous termination condition. A simple way to form an iterative scheme is Richardson iterations [4]

$$
\begin{equation*}
\mathrm{x}^{(\mathrm{k}+1)}=(\mathrm{I}-\mathrm{A}) \mathrm{x}^{(\mathrm{k})}+\mathrm{b} \tag{6}
\end{equation*}
$$

[4] Richardson iterations preconditioned with approximate inversion

$$
\begin{equation*}
x^{(k+1)}=(I-M A) x^{(k)}+M b \tag{7}
\end{equation*}
$$

Where matrix $M$ is called approximate inverse of $A$ if $\|I-M A\|<1$. A question that naturally arises is will the iterations converge to the solution of $\mathrm{Ax}=\mathrm{b}$. In this section, to begin with, some well-known iterative schemes are presented. Their convergence analysis is presented next. In the derivations that follow, it is implicitly assumed that the diagonal elements of matrix A are nonzero, i.e. $a_{i i} \neq 0$, if this is not the case, simple row exchange is often sufficient to satisfy this condition.

Theorem2.1. A matrix $A$ is called strictly diagonally dominant if:

$$
\sum_{j=1(j \neq i)}^{n}\left|a_{i j}\right|<\left|a_{i i}\right| \quad \text { for } \quad \mathrm{i}=1,2, \ldots \ldots \mathrm{n}
$$

Theorem2.2. A sufficient condition for the convergence of Jacobi and Gauss-Seidel methods is that the matrix $A$ of linear system $A x=b$ is strictly diagonally dominant [6]

Theorem.2.3. For any arbitrary matrix $A$, the necessary condition for the convergence of relaxation method is $0<w<2$. [9]

## 3. Materials and Methods

3.1. Jacobi-Method: Suppose we have a guess solution, say $\mathrm{x}^{(\mathrm{k})}$

$$
\mathrm{x}^{(\mathrm{k})}=\left[\begin{array}{llll}
x_{1}{ }^{(k)} & x_{2}{ }^{(k)} & x_{3}{ }^{(k)} \ldots \ldots \ldots \ldots x_{n}{ }^{(k)}
\end{array}\right]^{\mathrm{T}}
$$

for, $\mathrm{Ax}=\mathrm{b}$ : To generate an improved estimate starting from $\mathrm{x}^{(\mathrm{k})} ;$ consider the first equation in the set of equations $A x=b$, i.e.,

$$
\begin{equation*}
a_{11} x_{1}+a_{12} x_{2}+\cdots \ldots \ldots . a_{1 n} x_{n}=b_{1} \tag{8}
\end{equation*}
$$

Rearranging this equation, we can arrive at a iterative formula for computing, $\mathrm{x}_{1}{ }^{(\mathrm{k}+1)}$, as

$$
\begin{equation*}
x_{1}{ }^{(k+1)}=\frac{1}{a_{11}}\left[b_{1}-a_{12} x_{2}{ }^{(k)} \ldots \ldots-a_{1 n} x_{n}{ }^{(k)}\right] \tag{9}
\end{equation*}
$$

Similarly, using second equation from $A x=b$, we can derive

$$
\begin{equation*}
x_{2}{ }^{(k+1)}=\frac{1}{a_{22}}\left[b_{2}-a_{21} x_{1}{ }^{(k)}-a_{23} x_{3}{ }^{(k)} \ldots \ldots-a_{2 n} x_{n}{ }^{(k)}\right] \tag{10}
\end{equation*}
$$

In general, using $\mathrm{i}^{\text {th }}$ row of $\mathrm{Ax}=\mathrm{b}$; we can generate improved guess for the $\mathrm{i}^{\text {th }}$ element x of as follows

$$
\begin{equation*}
x_{i}{ }^{(k+1)}=\frac{1}{a_{i i}}\left[b_{2}-a_{i 1} x_{1}{ }^{(k)} \ldots-a_{i, i-1} x_{i-1}{ }^{(k)}-a_{i, i+1} x_{i+1}{ }^{(k)} \ldots-a_{i, n} x_{n}{ }^{(k)}\right] \tag{11}
\end{equation*}
$$

The above equation can also be rearranged as follows

$$
x_{i}{ }^{(k+1)}=x_{i}^{(k)}+\left(\frac{r_{i}(k)}{a_{i i}}\right)
$$

Where $\mathrm{r}_{\mathrm{i}}{ }^{(\mathrm{k})}$ is defined by equation (4). In matrix form, the method can be written as

$$
\mathrm{x}^{(\mathrm{k}+1)}=-\mathrm{D}^{-1}(\mathrm{~L}+\mathrm{U}) \mathrm{x}^{(\mathrm{k})}+\mathrm{D}^{-1} \mathrm{~b}
$$

The algorithm for implementing the Jacobi iteration scheme is summarized in Chart 1.
Chart 1: Algorithm for Jacobi Iterations

$$
\begin{gathered}
r_{i}=b_{i}-\sum_{j=1}^{n} a_{i j} x_{j} \\
x_{N i}=x_{i}+\left(\frac{r_{i}}{a_{i i}}\right)
\end{gathered}
$$

## END FOR

$$
\begin{gathered}
\delta=\|r\| /\|b\| \\
x=x_{N} \\
\mathrm{k}=\mathrm{k}+1
\end{gathered}
$$

## END WHILE

3.2. Gauss-Seidel Method: When matrix A is large, there is a practical difficulty with the Jacobi method. It is required to store all components of $x^{(k)}$ in the computer memory (as a separate variables) until calculations of $x^{(k+1)}$ is over. The Gauss-Seidel method overcomes this difficulty by using $\mathrm{X}_{\mathrm{i}}{ }^{(\mathrm{k}+1)}$ immediately in the next equation while computing $\mathrm{x}_{\mathrm{i}+1}{ }^{(\mathrm{k}+1)}$ :This modification leads to the following set of equations

$$
\begin{gather*}
x_{1}{ }^{(k+1)}=\frac{1}{a_{11}}\left[b_{1}-a_{12} x_{2}{ }^{(k)}-a_{13} x_{3}{ }^{(k)} \ldots \ldots a_{1 n} x_{n}{ }^{(k)}\right]  \tag{12}\\
x_{2}{ }^{(k+1)}=\frac{1}{a_{22}}\left[b_{2}-\left\{a_{21} x_{1}{ }^{(k+1))}\right\}-\left\{a_{23} x_{3}{ }^{(k)}+\cdots \ldots+a_{2 n} x_{n}{ }^{(k)}\right\}\right]  \tag{13}\\
x_{3}{ }^{(k+1)}=\frac{1}{a_{33}}\left[b_{3}-\left\{a_{31} x_{1}{ }^{(k+1))}+a_{32} x_{2}{ }^{(k+1))}\right\}-\left\{a_{34} x_{4}{ }^{(k)}+\cdots \ldots+a_{3 n} x_{n}{ }^{(k)}\right\}\right] \tag{14}
\end{gather*}
$$

In general, for $i$ 'th element of $x$, we have

$$
x_{i}^{(k+1)}=\frac{1}{a_{i i}}\left[b_{i}-\sum_{j=1}^{i-1} a_{i j} x_{j}^{(k+1)}-\sum_{j=i+1}^{n} a_{i j} x_{j}^{(k)}\right]
$$

To simplify programming, the above equation can be rearranged as follows

$$
\begin{gather*}
x_{i}^{(k+1)}=x_{i}^{(k)}+\left(\frac{r_{i}^{(k)}}{a_{i i}}\right)  \tag{15}\\
r_{i}^{(k)}=\left[b_{i}-\sum_{j=1}^{i-1} a_{i j} x_{j}^{(k+1)}-\sum_{j=i+1}^{n} a_{i j} x_{j}^{(k)}\right]
\end{gather*}
$$

where
In matrix form, the method can be written as

$$
\begin{equation*}
x^{(k+1)}=-(L+D)^{-1} U x^{(k)}+(L+D)^{-1} b \tag{16}
\end{equation*}
$$

The algorithm for implementing Gauss-Siedel iteration scheme is summarized in Chart2.

## Chart 2: Algorithm for Gauss Seidel Iterations

$$
\begin{gathered}
\delta=\|r\| /\|b\| \\
\mathrm{k}=\mathrm{k}+1
\end{gathered}
$$

## END WHILE

3.3. SUCESSASIVE OVER RELAXTION METHOD: Suppose we have a starting value say y, of a quantity and we wish to approach a target value, say $y^{*}$ by some method. Let application of the method change the value from y to $\mathrm{y} \wedge \cdot$ If $\mathrm{y}^{\wedge}$ is between y and $\mathrm{y}^{\wedge}$ which is even closer to y than $y^{*}$. Then we can approach $y^{*}$ faster by magnifying the change $\left(y^{\wedge}-y\right)$ [3]. In order to achieve this, we need to apply a magnifying factor $w>1$ and get

$$
\begin{equation*}
y^{*}=y+w\left(\mathrm{y}^{\wedge}-\mathrm{y}\right) \tag{17}
\end{equation*}
$$

This amplification process is an extrapolation and is an example of over-relaxation. If the intermediate value $\mathrm{y}^{\wedge}$ tends to overshoot target $\mathrm{y}^{*}$, then we may have to use $\mathrm{w}<1$; this is called under-relaxation. Application of over-relaxation to Gauss-Seidel method leads to the following set of equations

$$
\begin{equation*}
x_{i}^{(k+1)}=x_{i}^{(k)}+w\left[z_{i}^{(k+1)}-x_{i}^{(k)}\right] \quad \text { for } \mathrm{i}=1,2, \ldots \mathrm{n} \tag{18}
\end{equation*}
$$

Where $\mathrm{z}_{\mathrm{i}}{ }^{(\mathrm{k}+1)}$ are generated using the Gauss-Seidel method,

$$
\begin{equation*}
z_{i}^{(k+1)}=\frac{1}{a_{i i}}\left[b_{i}-\sum_{j=1}^{i-1} a_{i j} x_{j}^{(k+1)}-\sum_{j=i+1}^{n} a_{i j} x_{j}^{(k)}\right] \quad \text { for } \mathrm{i}=1,2 \ldots \mathrm{n} \tag{19}
\end{equation*}
$$

In matrix form, the method can be written as

$$
\begin{equation*}
x^{(k+1)}=(w L+D)^{-1}[(1-w) D-w U] x^{(k)}+w b \tag{20}
\end{equation*}
$$

Thus, in general, an iterative method can be developed by splitting matrix A . The steps in the implementation of the over-relaxation iteration scheme are summarized in Chart 3. It may be noted that w is a tuning parameter, which is chosen such that $1<\mathrm{w}<2$ [9]

Chart 3: Algorithm for Gauss Seidel Iterations

$$
\begin{aligned}
& \text { INITIALIZE: } \mathrm{b}, \mathrm{~A}, \mathrm{x}^{(0)}, \mathrm{k}_{\max }, \epsilon \\

## 4. Convergence Analysis of Iterative Methods

The convergence analysis can be carried out if the above set of iterative equations are expressed in the vector-matrix notation To discuss the convergence of the iterative methods (ii) .we study the behavior of the difference between the exact solution x and an approximate $x^{(k)}$. The exact solution x will satisfy

$$
\begin{equation*}
x=H x+c \tag{21}
\end{equation*}
$$

Where $\mathrm{H}=\|\mathrm{I}-\mathrm{MA}\|<1$, Subtracting (21) from (6) and substituting $\epsilon^{(k)}=x^{(k)}-x$, we get

From which we obtain

$$
\begin{array}{cc}
\epsilon^{(k+1)}=H \epsilon^{(k)} & , \mathrm{k}=0,1,2, \ldots \ldots \ldots \\
\epsilon^{(k)}=H^{(k)} \epsilon^{(0)} & \mathrm{k}=0,1,2, \ldots \ldots \ldots .
\end{array}
$$

Where we have assumed that the iteration matrix H remains constant for each iteration.We given few results above which we require for providing the convergence of the iterative methods.[1]

## 5. Numerical Experiments and Comparative discussion

In this section, we employ the various techniques obtained in this paper to solve system of linear simultaneous equations and compare them. We use the stopping criteria $\left|x_{k+1}-x_{k}\right|<\varepsilon$ and $\left|f\left(x_{k+1}\right)\right|<\varepsilon$, where $\varepsilon=10^{-15}$, for computer programs. All programs are written in Matlab2009a. The results are presented in Table1to3. Example1. Let us consider the system of linear simultaneous equations of $\mathrm{n}=4$ variables.

$$
\begin{aligned}
& 3.112 x+0.5756 y-0.1565 z-0.0067 t=1.5710 \\
& 0.5756 x+2.938 y+0.1103 z-0.0015 t=-0.9275 \\
&-0.1565 x+0.1103 y+4.127 z+0.2015 t=-0.06502 \\
&-0.0067 x-0.0015 y+0.2051 z+4.133 t=-0.0177
\end{aligned}
$$

Table 3 shows that the iteration data obtained for SOR method .it was observed that the numerical Solution of the linear simultaneous equation converges at the 22 iteration with error level of 0.000000000000005 when optimal factor $w=1.2$

Example-2 Let us consider another the system of linear simultaneous equations of $n=5$ variables

$$
\begin{aligned}
10 v & +w+x-2 y+z=-1, v-20 w-2 x+y+z=20, v+w+10 x-y-z=1 \\
& -v+2 w+x+50 y+z=2, v+w+x+y+100 z=-1
\end{aligned}
$$

The solution of above equations are converges $16,11,24$ iterations respectively by the above techniques up to error level of $\varepsilon=10^{-15}$ which are given below.

$$
\begin{aligned}
& \mathrm{v}=-0.00364280090102 \\
& \mathrm{w}=-1.01743940692132 \\
& \mathrm{x}=0.20949210878712 \\
& \mathrm{y}=0.07648785763481 \\
& \mathrm{z}=-0.00264897758600
\end{aligned}
$$

Thus we can solve the system of linear simultaneous equations of more variable which are diagonally dominant in coefficient matrix by the above techniques.
5.1. Executing time: The execution time of a given task is defined as the time spent by the system executing that task, including the time spent executing run time or system services on its behalf. Table 4: Execution time comparison for iterations data of various techniques

| S/No. | Techniques | Number of iterations |  | (Elapsed time) |  |
| :--- | :---: | :---: | :---: | :--- | :--- |
|  |  | Example1 | Example2 | Example1 | Example2 |
|  | Jacobi | 22 | 16 | 0.015000 | 0.02000 |
| 2. | Seidel | 12 | 11 | 0.000140 | 0.01500 |
| 3. | SOR | 22 | 24 | 0.016000 | 0.02500 |

Thus from the above discussions we see that the Jacobi and SOR method is taking more time in comparison to that of Seidel method to run the program. [11]. SOR method has more error than other Since the Seidel method requires less number of iterations and Jacobi and SOR method
required more iterations with error level 0.000000000000005 with optimal factor $w=1.2$ Thus we see that the overall performance of the iterative techniques are in this manner.

SOR method $\leq$ Jacobi method $<$ Gauss Seidel method

## CONCLUSION

The above plot is shows the result obtained from different algorithm. Consequently, we can see that Gauss Seidel Technique is more accurate at large scale with different parameters such as running time factor and number of iterations and error level. Based on our results and discussions, we now conclude that the Seidel method is formally the most effective of the Jacobi and SOR method, we have considered here in the study. Analysis of efficiency from the numerical computation shows that Jacobi and SOR method converges slowly. Thus these methods have great practical utilities. One can easily adopt these MATLAB codes as needed for a different type of problem linear simultaneous equations of more order like $6 \times 6$ and so on. And also can use linear simultaneous differential equation for equilibrium problem in applied mathematics.
