**Abstract.** In this paper, we investigate the Bruck-Reilly extension of monoids and the Clifford semigroups and then determine when they are E-unitary. This motivates us to characterize E-unitary bisimple inverse  $\omega$ -semigroups and E-unitary simple inverse  $\omega$ -semigroups respectively.

**Keywords:** Bruck-Reilly extensions; Clifford semigroups; E-unitary semigroups;  $\omega$ -semigroups.

**2010 AMS Subject Classification:** 20M18.

### 1. Introduction and Preliminaries

E-unitary inverse semigroups form one of the most important classes of inverse semigroups. Indeed McAlister [2], [3] proved two remarkable theorems concerning these semigroups: (1) every E-unitary inverse semigroup admits a faithful representation as a P-semigroup (which is reminiscent of a semidirect product of a semilattice and a group), and (2) every inverse semigroup is an idempotent separating homomorphic image of an E-unitary inverse semigroup. Munn and Reilly [4] devised a different proof of both of these theorems.

In this paper, we study E-unitary inverse  $\omega$ -semigroups using the Bruck-Reilly extension of monoids and the Clifford semigroups. In particular, we prove that the Bruck-Reilly extension of monoids is an E-unitary bisimple inverse  $\omega$ -semigroup while the Clifford semigroup is an E-unitary simple inverse  $\omega$ -semigroup.

Now we recall some definitions which will be useful in the sequel.

We refer the reader to [1] for more detailed knowledge.

**Definition 1.1.** Let  $S$  be an inverse semigroup and let  $a, b \in S$ . Then  $a \leq b$  if there exists an idempotent  $e$  in  $S$  such that  $a = be$ .

**Definition 1.2.** An inverse semigroup is E-unitary if  $e \leq a$  (where  $e$  is an idempotent) implies  $a^2 = a$ .

The class of E-unitary inverse semigroups are important as many inverse semigroups are E-unitary.

**Example 1.3.** Groups are E-unitary inverse semigroups.

**Example 1.4.** Let  $B = \mathbb{N}^0 \times \mathbb{N}^0$  ( $\mathbb{N}^0$  is the set of non negative integers) and for  $(m, n), (p, q) \in B$ ,

$$(m, n)(p, q) = (m - n + t, q - p + t), \text{ where } t = \max(n, p).$$

Then  $B$  is a semigroup and is known as the bicyclic semigroup. It can be shown that  $B$  is an inverse semigroup and the set of its idempotents  $E(B) = \{(m, m) : m \in \mathbb{N}^0\}$ .

Let  $(m, n) \in B$  and let  $(r, r) \in E(B)$ . Now suppose  $(r, r) \leq (m, n)$ . Then

$$(m, n)(r, r) = (m - n + t, r - r + t) = (m - n + t, t),$$

where  $t = \max(n, r)$ . Since  $(m, n)(r, r)$  is an idempotent, it must be equal to  $(u, u)$  for some  $u \in \mathbb{N}^0$ .

This implies that  $m - n + t = u$  and  $t = u$ , so  $m - n + t = t$ . Hence  $m = n$  and therefore  $(m, n) \in E(B)$ . So  $B$  is E-unitary.

**Definition 1.5.** Let  $S$  be a semigroup and  $E(S)$  be its sets of idempotents. Then  $S$  is an  $\omega$ -semigroup if and only if there exists a one-to-one mapping  $\theta$  of  $E(S)$  onto  $\mathbb{N}^0$  such that for any elements  $e, f \in E(S)$ ,  $e\theta \leq f\theta$  if and only if  $f \leq e$ . Thus, if  $S$  is an  $\omega$ -semigroup, then we write

$$E(S) = \{e_m : m \in \mathbb{N}^0\} \text{ where } e_m \leq e_n \Leftrightarrow m \geq n \text{ or } E(S) = \{e_i : i = 0, 1, 2, \dots\} \text{ such that } e_0 > e_1 > e_2 \dots \dots$$

**Definition 1.6.** Given a map  $\theta: S \rightarrow P$  we define

$$\text{Ker } \theta = \{(x, y) \in S \times S : x\theta = y\theta\}$$

and call this the kernel of the map.

**Definition 1.7.** Let  $S$  be an inverse semigroup with semilattice of idempotents  $E(S)$ . Then for all  $a, b \in S$ ,  $a \sigma b \Leftrightarrow ae = be$  for some  $e \in E(S)$ .

**Definition 1.8.** Let  $S$  be a semigroup and let  $a, b \in S$ . We define the following relations on  $S$

$$a \mathcal{L} b \Leftrightarrow S^1 a = S^1 b, a \mathcal{R} b \Leftrightarrow a S^1 = b S^1, a \mathcal{J} b \Leftrightarrow S^1 a S^1 = S^1 b S^1,$$

$$a \mathcal{H} b \Leftrightarrow a \mathcal{L} b \text{ and } a \mathcal{R} b \text{ i.e } \mathcal{H} = \mathcal{L} \cap \mathcal{R}, a \mathcal{D} b \Leftrightarrow (\exists c \in S) \text{ such that } a \mathcal{L} c \text{ and } c \mathcal{R} b.$$

The relations  $\mathcal{L}, \mathcal{R}, \mathcal{J}, \mathcal{H}, \mathcal{D}$  are called Green's relations.

**Remark 1.9.** i) It is more or less easy to see that all Green's relations are equivalences.

ii) In any commutative semigroup,  $\mathcal{H} = \mathcal{L} = \mathcal{R} = \mathcal{D} = \mathcal{J} = G \times G$ .

Since for any elements  $a \in G$  we have  $G^1 a = G$  and  $a G^1 = G$ .

iii)  $\mathcal{D}$  is defined such that it is the smallest equivalence containing  $\mathcal{L}$  and  $\mathcal{R}$ .

iv) If we regard relations as subsets of  $S \times S$  we have the inclusions  $\mathcal{H} \subseteq \mathcal{L}, \mathcal{R} \subseteq \mathcal{D} \subseteq \mathcal{J}$ .

The last inclusion follows from iii) and the fact that  $\mathcal{L}, \mathcal{R} \subseteq \mathcal{J}$ .

A proof of the above statements can be found in [1].

**Definition 1.10.** A (left, right) proper ideal  $I$  of a semigroup  $S$  is an (left, respectively, right) ideal such that  $I \neq S$ . That is, such that  $I \subseteq S$  and  $I \neq S$ . A semigroup  $S$  is called right simple if it contains no proper right ideals, dually a semigroup  $S$  is called left simple if it contains no proper left ideals, and a semigroup  $S$  is called simple if it has no two-sided ideals.

It is easy to see that a semigroup  $S$  is right (left) simple if and only if  $\mathcal{R} = S \times S$  ( $\mathcal{L} = S \times S$ ), and simple if and only if  $\mathcal{J} = S \times S$ . A semigroup is called bisimple if  $\mathcal{D} = S \times S$ .

Since in a group  $G$  we have that  $\mathcal{L} = \mathcal{R} = G \times G$ , we conclude that groups are left and right simple. Thus  $G$  is simple.

The following example shows that the bicyclic semigroup is simple as well as bisimple.

**Example 1.11.** Let  $B$  be a bicyclic semigroup. Let  $I \subseteq B$  be an ideal, and  $(m, n) \in I$ . Then we have  $(0, n) = (0, m)(m, n) \in I$ . Hence  $(0, 0) = (0, n)(n, 0) \in I$ .

Take any arbitrary element  $(a, b) \in B$ . Then  $(a, b) = (a, b)(0, 0) \in I$ , thus,  $B \subseteq I$ . Therefore  $B = I$ , so  $B$  is simple. Infact more is true: let  $(m, n), (k, l) \in B$ . Then

$$(m, n) \mathcal{R} (m, l) \mathcal{L} (k, l),$$

So that  $(m, n) \mathcal{D} (k, l)$ . Hence  $B$  is bisimple.

## 2. Bisimple inverse $\omega$ -semigroups

Let  $M$  be a monoid with identity  $e$  and  $\theta : M \rightarrow M$  be a morphism. Let  $\theta^0$  be the identity map on  $M$  and let  $S$  consist of set  $S = \mathbb{N}^0 \times M \times \mathbb{N}^0$  (where  $\mathbb{N}^0$  denote the set of non-negative integers) with multiplication defined by the rule

$$(m, x, n)(p, y, q) = (m - n + t, x\theta^{t-n}y\theta^{t-p}, q - p + t),$$

where  $t = \max(n, p)$ , for  $(m, x, n), (p, y, q) \in S$ .

Under this operation,  $S = \mathbb{N}^0 \times M \times \mathbb{N}^0$  is a semigroup and it is the one we refer to as the Bruck-Reilly extensions of the monoid  $M$ . This semigroup is usually denoted by  $BR(M, \theta)$ .

The following useful results are proved in [1].

**Lemma 2.1.** Let  $S = BR(M, \theta)$  be the Bruck-Reilly extension of a monoid  $M$ . Suppose that  $(m, x, n)$  and  $(p, y, q)$  are elements of  $S$ . Then

i)  $S$  is a simple semigroup with identity  $(0, e, 0)$ .

ii)  $(m, x, n) \mathcal{D} (p, y, q)$  if and only if  $x \mathcal{D}(M)y$ .

iii) The element  $(m, x, n)$  is an idempotent in  $S$  if and only if  $m = n$  and  $x^2 = x \in M$ .

iv)  $S$  is inverse if and only if  $M$  is inverse.

v)  $(m, x, n) \geq (p, y, q)$  if and only if  $m + t = p$ ,  $n + t = q$  for some  $t \in \mathbb{N}^0$  and for some  $e \in E(M)$ .

If we consider the special case of the Bruck-Reilly extension where  $M$  is a group (with identity  $e$ ). By (ii) and (iv),  $BR(M, \theta)$  then becomes a bisimple inverse semigroup with identity  $(0, e, 0)$  and  $\theta$  an endomorphism of  $M$ . From (v), we know that

$$(0, e, 0) > (1, e, 1) > (2, e, 2) > \dots$$

Since a group morphism maps the identity element to the identity element.

Hence  $BR(M, \theta)$  is a bisimple inverse  $\omega$ -semigroup. The converse of this theorem also holds.

**Theorem 2.2 (structure theorem).** Let  $M$  be a group and let  $\theta$  be an endomorphism of  $M$ . Let  $S = BR(M, \theta)$  be the Bruck-Reilly extension of  $M$  determined by  $\theta$ . Then  $S$  is a bisimple inverse  $\omega$ -semigroup. Conversely, every bisimple inverse  $\omega$ -semigroup is isomorphic to one of this type.

In the next Proposition, we now establish a connection between E-unitariness of  $M$  and  $BR(M, \theta)$ .

**Proposition 2.3.** Let  $M$  be an inverse monoid and let  $\theta$  be an endomorphism into the group of units of  $M$ . Then  $S = BR(M, \theta)$  is E-unitary if and only if  $M$  is E-unitary and  $\sigma = \ker \theta$ .

**Proof.** Let  $BR(M, \theta)$  be E-unitary. From Lemma 2.1(iii), we know that the idempotents of  $S$  are of the form  $(m, e, m)$ , where  $e \in E(M)$ . Let  $e, ae \in E(M)$ . Then  $(0, e, 0), (0, ae, 0) \in E(S)$ . But we have that  $(0, ae, 0) = (0, a, 0)(0, e, 0) \leq (0, a, 0)$  and so  $(0, a, 0) \in E(S)$  by assumption. This implies in particular that  $a \in E(M)$ . Hence  $M$  is E-unitary.

Let  $x, y \in M$  such that  $x \sigma y$ . Then  $xe = yf$  for  $e, f \in E(M)$ . Since idempotents are mapped to idempotents and since the only idempotent in the group of units is the identity element, we get

$$\begin{aligned} x\theta &= x\theta e\theta = (xe)\theta \\ &= (yf)\theta = y\theta f\theta = y\theta. \end{aligned}$$

Hence  $\sigma \subseteq \ker \theta$ . The reverse inclusion and the converse of the proof is clear.

As an application of Proposition 2.3, we can now characterize E-unitary bisimple inverse  $\omega$ -semigroups with the help of Theorem 2.2.

**Theorem 2.4.** A bisimple inverse  $\omega$ -semigroup is E-unitary if and only if  $\theta$  is one-to-one.

**Proof.** It is clear from Proposition 2.3 since every group is E-unitary with the  $\sigma$ -relation being the equality relation.

### 3. Simple inverse $\omega$ -semigroups

In this section, we obtain a result analogous to Theorem 2.4. But first we have the following useful definitions.

**Definition 3.1.** An element  $a \in S$  is called central if  $ax = xa$  for all  $a \in S$ .

**Definition 3.2.** We call a semigroup a Clifford semigroup if it is regular and its idempotents are central. Obviously, a Clifford semigroup is inverse, since in particular its idempotents commute. Its structural characterization is given below.

**3.3 The Structural Characterization** [1]. Let  $E(S)$  be a semilattice and let  $\{G_e : e \in E(S)\}$  be a family of disjoint groups indexed by the elements of  $E(S)$ . We denote the identity element of  $G_e$  by  $1_e$ . For each pair  $e, f \in E(S)$  such that  $e \geq f$  let  $\varphi_{e,f} : G_e \rightarrow G_f$  be a group morphism such that the following conditions hold:

- i)  $\varphi_{e,e}$  is the identity morphism on  $G_e$
- ii) if  $e \geq f \geq g$  then  $\varphi_{f,g}\varphi_{e,f} = \varphi_{e,g}$

We endow the set  $\bigcup_{e \in E(S)} G_e$  with a product defined by

$$x \circ y = (x\varphi_{e,ef})(y\varphi_{f,ef})(x \in G_e, y \in G_f).$$

It is shown in [1] that  $(\bigcup_{e \in E(S)} G_e, \circ)$  is a Clifford semigroup. Infact this semigroup is called a strong semilattice of groups and it is denoted by  $S(E; G_e; \varphi_{e,f})$ .

We know from Theorem 2.2 that the Bruck-Reilly extension  $BR(M, \theta)$  of a monoid  $M$  is a bisimple inverse  $\omega$ -semigroup. To find a structure theorem for simple inverse  $\omega$ -semigroups, we examine a particular type of Clifford semigroups of the Bruck-Reilly extension.

We now introduce this construction.

**3.4 Construction.** Let  $Y = \{0, 1, \dots, d-1\}$  be a chain with the reversed usual order. To simplify the notation we shall use the convention to denote by  $\leq$  the usual order of the natural numbers, whereas by  $\wedge$  we refer to the order of the chain, for example  $4 \leq 5$  but  $4 \wedge 5 = 5$ . For every  $i \in Y$  let  $G_i$  denote a group such that all the groups  $G_i$  are disjoint. Put  $M := \bigcup_{i=0,1,\dots,d-1} G_i$ . For every  $0 \leq i \leq d-2$  choose and fix a morphism  $\alpha_{i,j} : G_i \rightarrow G_{i+1}$ . Moreover, we define for every  $0 \leq i < j \leq d-1$

a new morphism  $\alpha_{i,j} : G_i \rightarrow G_j$  by the rule

$$\alpha_{i,j} = \gamma_{j-1} \circ \gamma_{j-2} \circ \dots \circ \gamma_i.$$

Putting the identity of  $G_i$  as  $\alpha_{i,i}$  we have

$$\alpha_{j,k} \circ \alpha_{i,j} = \alpha_{i,k} (i \leq j \leq k).$$

From 3.3, we know that the strong semilattice of groups  $(M, \circ)$  is a Clifford semigroup. We can say that the semilattice is a chain isomorphic to  $Y$ . The idempotents of  $M$  are the identity elements of the groups  $G_i$  denoted by  $e_0, e_1, \dots, e_{d-1}$ . Recall that identity elements are mapped to identity elements by group morphisms and notice that  $e_0$  is the identity element of the monoid  $M$  :

$$\begin{aligned} \forall i \forall x \in G_i : e_0 x &= \alpha_{0,0 \wedge i}(e_0) \alpha_{i,0 \wedge i}(x) = \alpha_{0,i}(e_0) \alpha_{i,i}(x) \\ &= e_i x = x. \end{aligned}$$

A similar argument shows that  $xe_0 = x$  for all  $x \in M$ . Furthermore, a straightforward calculation yields  $e_0 > e_1 > \dots > e_{d-1}$ .

We shall refer to  $M$  as a finite chain of groups of length  $d$ .

Let  $M$  be a finite chain of groups of length  $d$ . Notice that the group of units of  $M$  is  $G_0$  because a product in which an element  $x \in G_i$  is involved does necessarily lie in  $G_j$  for some  $j \geq i$ . Now let  $S = BR(M, \theta)$ , where  $\theta$  is a morphism from  $M$  to  $G_0$ . By Lemma 2.1 (i),  $S$  is a simple inverse semigroup since  $M$  is inverse. Also by Lemma 2.1 (ii) the  $\mathcal{D}$ -classes of  $S$  are the subsets  $\mathbb{N}^0 \times G_i \times \mathbb{N}^0$  ( $i = 0, 1, \dots, d-1$ ).

**Lemma 3.5.**  $S$  is an  $\omega$ -semigroup.

**Proof.** Let  $(m, e_i, m), (n, e_j, n)$  be two idempotents. We assume without loss of generality that  $m \geq n$  and distinguish between two cases :

Case i. For  $m = n$  we have

$$(m, e_i, m) \leq (m, e_j, m) \Leftrightarrow (m, e_i, m)(m, e_j, m) = (m, e_i, m).$$

Having in mind that  $(m, e_i, m)(m, e_j, m) = (m, e_i e_j, m)$ , this is the case if and only if  $e_i \leq e_j$  in  $M$ , i.e. if and only if  $i \wedge j = i$ .

Case ii. For  $m < n$  we have  $\theta^{m-n}(e_j) = e_0$ , the identity of  $M$ . Hence

$$(m, e_i, m)(n, e_j, n) = (m, e_i \theta^{m-n}(e_j), m) = (m, e_i, m)$$

and so  $(m, e_i, m) < (n, e_j, n)$  regardless of the values of  $i$  and  $j$ . In effect, the idempotents of  $S$  form a chain

$$\begin{aligned} & (0, e_0, 0) > (0, e_1, 0) > \dots > (0, e_{d-1}, 0) > \\ & (1, e_0, 1) > (1, e_1, 1) > \dots > (1, e_{d-1}, 1) > \\ & \cdot \\ & \cdot \\ & \cdot \\ & (d-1, e_0, d-1) > (d-1, e_1, d-1) > \dots > (d-1, e_{d-1}, d-1). \end{aligned}$$

Thus  $S = BR(M, \theta)$  is a simple inverse  $\omega$ -semigroup. The converse of this also holds.

**Theorem 3.6** [1]. Let  $M$  be a finite chain of groups of length  $d$  ( $\geq 1$ ). If  $\theta$  is a morphism from  $M$  into the group of units of  $M$ , then the Bruck-Reilly extension  $BR(M, \theta)$  of  $M$  determined by  $\theta$  is a simple inverse  $\omega$ -semigroup with  $d$   $\mathcal{D}$ -classes. Conversely, every simple inverse  $\omega$ -semigroup is isomorphic to one of this type.

Our next task is to characterize the E-unitary simple inverse  $\omega$ -semigroups. From Theorem 3.6, we know that within  $M$  the multiplication is defined via morphism  $\gamma_i : G_i \rightarrow G_{i+1}$  ( $i = 0, \dots, d-2$ ). From Proposition 2.3, we can say exactly when  $BR(M, \theta)$  is E-unitary, namely when  $M$  is E-unitary and  $\sigma_M =$

$\text{Ker } \theta$ . In order to obtain a more elegant criterion we formulate a Lemma that enables us to know when a Clifford semigroup is E-unitary and examine the  $\sigma$ -relation on the finite chain of groups.

**Lemma 3.7** [5]. Let  $S = S(E, G_e, \varphi_{e,f})$  be a Clifford semigroup. Then  $S$  is E-unitary if and only if the connecting morphisms  $\varphi_{e,f}$  are one-one.

**Lemma 3.8.** Let  $S = S(E, G_e, \varphi_{e,f})$  be a Clifford semigroup. Then  $a \sigma b$  if and only if there exists  $l \in E$  :  $a\varphi_{e,l} = b\varphi_{f,l}$  ( $a \in G_e, b \in G_f$ ).

**Proof.** The proof is clear.

**Theorem 3.9.** With the notation used in 3.4, a simple inverse  $\omega$ -semigroup  $BR(M, \theta)$  is E-unitary if and only if  $\gamma_i$  is one-to-one for all  $i \in \{0, \dots, d-2\}$  and  $a\theta = b\theta$  if and only if  $a\alpha_{j,k} = b$  ( $a \in G_j, b \in G_k, j \leq k$ ).

**Proof.** We know from Proposition 2.3 that  $S = BR(M, \theta)$  is E-unitary if and only if  $M$  is E-unitary and  $\sigma_M = \text{Ker } \theta$ . From Lemma 3.7 and Lemma 3.8 it follows that this is the case exactly when all connecting morphisms are one-to-one and  $a\theta = b\theta$  if and only if there exists  $l \geq j, k : a\alpha_{j,l} = b\alpha_{k,l}$  ( $a \in G_j, b \in G_k$ ). But  $S = BR(M, \theta)$  is not just any Clifford semigroup. It is a finite chain of groups. The rest of the Proof is clear.

### Conflict of Interests

The authors declare that there is no conflict of interests.
